## Supplementary Materials: A Novel Local Search Algorithm for the Vertex Bisection Minimization Problem

## 1 Deep Analysis of the Two-Manner Based Local Search

In this section, we present a deep analysis of the two-manner-based local search. Specifically, we evaluate a total of nine combinations of swap operations. First, we present the execution condition for the swap operation (Line 5 in Algorithm 5) in CELS and another two different execution conditions for the swap operation as follows:

•  $|VM(D)| \leq VM(D_{\text{best}})$ ,

- $|VM(D)| \leq VM(D_{\text{best}}) + 1$ ,
- $|VM(D)| \le VM(D_{\text{best}}) + 2$ .

Additionally, we present the swap rule utilized by CELS and another two alternate swap rules , where the swap rules become gradually greedy:

- Swap Rule: Vertices with the lowest  $\Delta_{\text{drop}}(D,v)$  from  $B \setminus V_{\text{lock}}$  are stored in  $S_B$ , and vertices with the lowest  $\Delta_{\text{add}}(D,v)$  from  $B' \setminus V_{\text{lock}}$  are stored in  $S_{B'}$ . If either set contains more than K vertices, we randomly retain K vertices in the corresponding set, where K is a predefined parameter. Then, we select a pair of vertices  $(v,u) := \arg\min_{v \in S_B, u \in S_{B'}} \Delta_{\text{swap}}(D,v,u)$ , breaking ties randomly.
- Swap Rule 1: Vertices with the lowest  $\Delta_{\text{drop}}(D,v)$  from  $B \setminus V_{\text{lock}}$  are stored in  $S_B$ , and vertices with the lowest  $\Delta_{\text{add}}(D,v)$  from  $B' \setminus V_{\text{lock}}$  are stored in  $S_{B'}$ . Then, we directly select a pair of vertices  $(v,u) := \arg\min_{v \in S_B, u \in S_{B'}} \Delta_{\text{swap}}(D,v,u)$ , breaking ties randomly.
- Swap Rule 2: A pair of vertices is selected as  $(v,u) := \arg\min_{v \in B \setminus V_{lock}, u \in B' \setminus V_{lock}} \Delta_{\mathrm{swap}}(D,v,u)$ , breaking ties randomly.

By combining the three execution conditions with the three swap rules, we generate nine types of swap operations, one of which is adopted by CELS. We then implement the other eight modified versions of the swap operation in CELS under the same settings, and compare the best solutions obtained by CELS with those produced by each corresponding algorithm. The results are summarized in Table 1. From Table 1, it is clear that the swap operation used in CELS outperforms the other swap operations, indicating the effective design of the swap operation in CELS.

## 2 Detailed Results of All Algorithms

We present the results of CELS and the comparative algorithms in Tables 2–5. For each instance, min represents the smallest size achieved by each algorithm, while avg indicates the average size obtained across 10 runs. If min equals avg, the average value is omitted. The Pre\_best column refers to the best results previously reported in the literature. In the tables, bold values highlight the best solutions achieved among all algorithms.
